ROBOT DOCKING STATION AND ROBOT FOR USE THEREWITH

Technical Field

The present invention is directed to robotics. In particular, the present invention is directed to docking stations for robots that are of use outdoors, and for robots for use with these docking stations, such as robots that function as lawn mowers.

Summary

The present invention provides a docking station for a robot, such as a robotic lawnmower. The docking station is particularly suited for outdoor use, but can also be used indoors if desired.

An embodiment of the present invention is directed to a robot having at least one contact (for example, typically two contacts), at least a portion of the contact extending from the robot, a control system in communication with the at least one contact, and a power supply (for example, a battery or batteries) for the robot. The power supply is electronically linked to the control system and the at least one contact. The control system is configured for permitting recharging of the power supply (battery or batteries of the robot) through the at least one contact, when a predetermined voltage on the at least one contact is detected. The robot can be, for example, a robotic lawnmower. The predetermined voltage is at least a threshold voltage, that is, for example, at least 25 Volts.

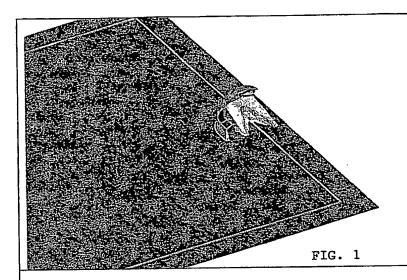

Another embodiment of the present invention is directed to a docking station for a robot. The docking station has a portion configured for receiving a robot, and a system for providing power to the robot for recharging the robot. The system has receptors configured for contacting at least one docking contact (or contact) on the robot (the robot, for example, typically has two docking contacts or contacts) and transmitting a voltage therethrough. This voltage is typically at least a threshold voltage (for example, at least approximately 25 Volts) detectable by the control system of the robot that a docking contact has occurred, whereby the robot is now suitable for docking, as well as operations associated with docking, for example, recharging. The receptors include at least one leaf. For example, there are typically two leafs corresponding to each of the docking contacts

Attorney Docket No. 67014 Page 1 of 12 (or contacts) on the robot. The leafs are typically rigid and connected to a flexible suspension. The docking station also has a control system in communication with the power providing system. The control system is configured for communication with at least one tap of an irrigation system, the tap being timer controlled, and coupled with the receptor for sending a signal to the robot for initiating operation of the robot. The robot used with this docking station is, for example, a robotic lawnmower.

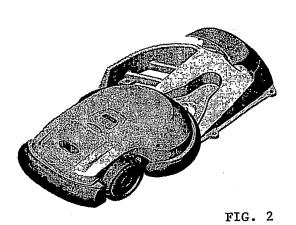

Attorney Docket No. 67014 Page 2 of 12

Detailed Description

Drawing Figs. 1-13 and their accompanying captions are part of this detailed description.

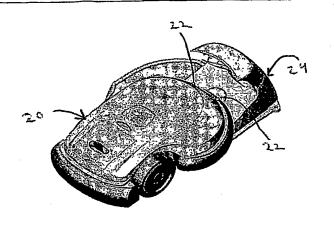

The docking station is placed over the perimeter wire, and the robot can dock while following the wire (the 'edge' mode). The arc ('docking fence') prevent the robot from climbing the docking from the wrong direction during are scanning.

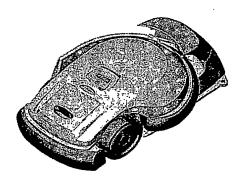

When the robot reaches the docking station, and climbs the ramp, it first sense a 'drop off' event, when the front wheel drops in to the valley in the middle of the base..

Attorney Docket No. 67014 Page 3 of 12

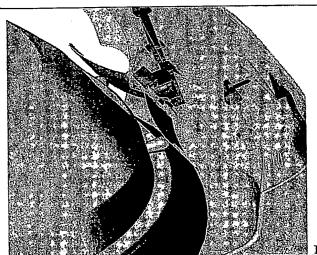

The robot than continues to drive slowly, seeking for signal from the docking contacts when those touch the docking leafs. If a good contact has not been made, the robot will get a bumper event and will than back-off and try to re-dock.

FIG. 3

When the robot sense a voltage over the docking contacts and stops, and starts the charging process.

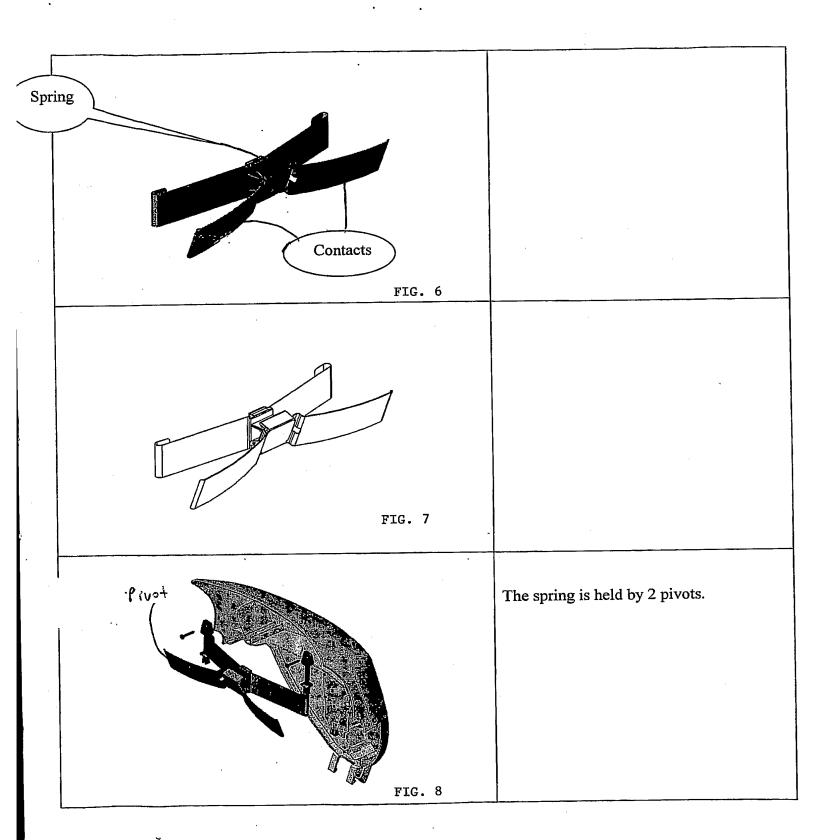

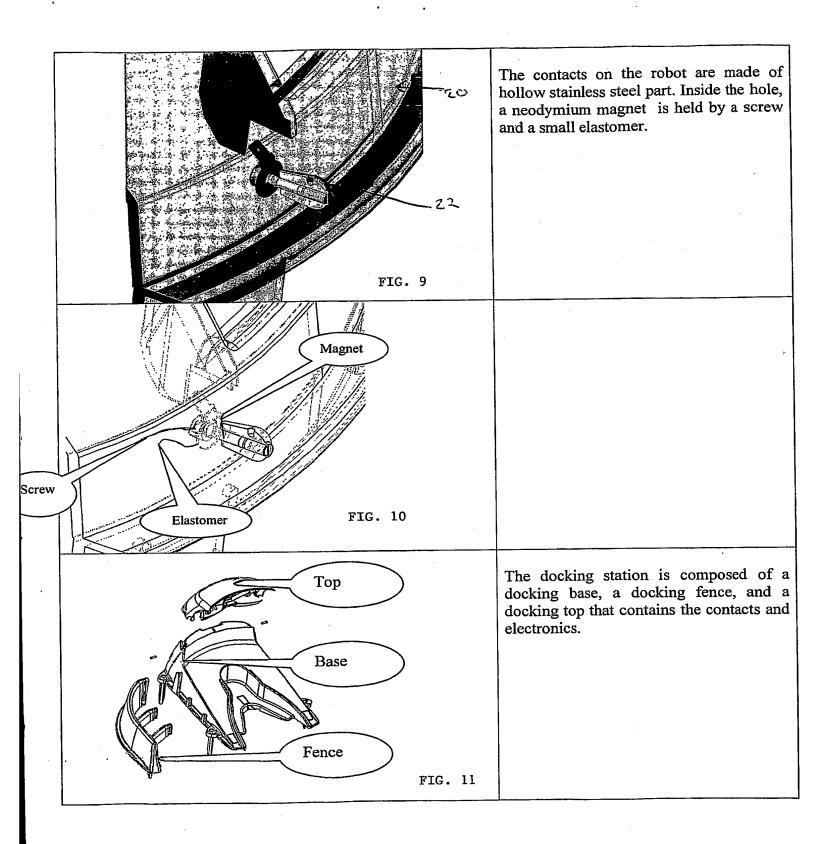

The docking leafs are suspended in a manner the robot can both over travel after touching the contacts and also compensate for angular misalignments.

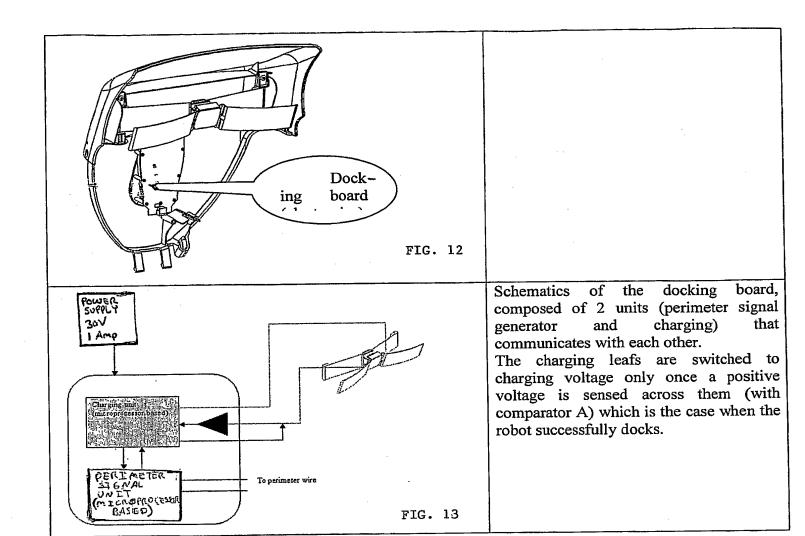

BTO E

Attorney Docket No. 67014 Page 4 of 12

Attorney Docket No. 67014 Page 6 of 12

A robot suitable for use with the docking station is a robotic lawn mower, for example, the robot disclosed in commonly owned U.S. Patent No. 6,443,509, incorporated by reference herein, and Robotic Lawnmower Model Numbers RL 500, RL 550, RL 800 and RL 850, from Friendly Robotics (the trading name of the owner of this application) of Pardesiya, Israel. All of the aforementioned robots are modified with docking contacts 22, for example, typically two docking contacts, at the front end of the robot, electronically linked (e.g., connected or coupled) to the control system (main control system) of the robot 20, and the power supply (batteries and associated components), to allow for charging of the power system once a sufficient contact is made (as determined by the control system, for example, there is at least a threshold voltage of, for example, as least 25 Volts, on the docking contacts 22), as shown, for example, in Figs. 3 and 9. Additionally, the front wheel of the robot is slideably mounted in a vertical orientation, such that when the mechanism on which the front wheel is mounted slides or drops downward to a predetermined level (also caused by lifting the body of the robot 20 at its front end), this mechanism is out of contact with a sensor, linked to the control system, whereby the control system signals the movement system (or drive system) to stop movement of the robot.

Detection of docking is initiated upon a 'drop off' event, that occurs when the unit or robot 20 climbs the docking base of the docking station 24 (Fig. 3). The climbing causes the front wheel, to drop downward, this dropping detected by the control system of the robot. The control system then signals the movement system (or drive system) to slow movement of the robot. The robot slows down and either a docking contact is made or there is a bumper event. If there is a docking contact, the docking contacts 22 are in contact with the leafs of the docking station, such that at least a threshold voltage (for example, at least 25 Volts) is then detected by the control system (activating the docking contacts 22). If this threshold voltage is not detected, there will be a bumper event (programmed into the control system by sensors on the bumper linked to the control system), where the robot 20 backs away from the docking station and attempts to redock. When there is a docking contact or bumper event, this is detected by the control system of the robot, that signals the drive (movement) system to stop.

Attorney Docket No. 67014 Page 8 of 12 The docking contacts are turned on (activated) by the charging voltage only when they sense a voltage (when the robot touches the docking contacts) of at least the threshold voltage (for example, at least 25 Volts). This prevents accidental shortening of the leafs when the robot is not docked. The perimeter signal is turned off whenever the robot docks. The turning on and off of the perimeter signal is typically controlled by the control system of the docking station.

The perimeter signal is turned on once a signal from the robot is detected. This signal is based on turning on and off the charging switch on the robot, at a certain frequency, thus, drawing alternating current from the docking board of the control system of the docking station (the docking board monitors the charging current).

It is also possible to turn on and off the perimeter signal manually, through a switch on the docking board of the docking station. The control system of the docking station can also be programmed to automatically control activation and deactivation (turning ON and OFF) of the perimeter signal.

The docking contacts (or contacts) 22 (Fig. 3) on the robot are made, for example, of stainless steel, and enclose a magnet. The docking station contact leafs are made of, for example, 304 stainless steel (para-magnetic). The leafs are typically mounted on a flexible suspension system. When the contacts get near the leafs, the leafs are pulled by the magnet in the contact, thus shortening the time of semi-contact if the leafs are wet or dirty. This substantially inhibits corrosion, dirt and other particulates from building on the leafs (on a bad, wet contact, some current flows through the water and rapidly extract salts from the water thus creating a non-conductive layer on the contacts that looks like corrosion. Another effect of the magnet is to maintain a good contact if the robot slips back slightly while stopping at the docking station.

The robot can be set to resume operation (or begin operation) from the docking station upon a triggering signal, typically recognized by the control system of the robot. This triggering signal can be timed in the control system of the robot, manually sent to or activated on the robot. This triggering signal can also be programmed into the control system of the docking station, or manually sent to or activated on the docking station. The docking station would then send a signal to the robot for its starting up and leaving the docking station to resume operation. The activation of this triggering signal, typically

Attorney Docket No. 67014 Page 9 of 12 also turns on the perimeter switch. Activation of the triggering signal can be at any desired time, for example, when mowing is desired. This can be at daily, weekly or even monthly intervals, depending on the kind of mowing needed and the season of the year.

There is also an external trigger connected to the docking board of the control unit of the docking station, that will initiate robot operation, by sending a signal to the control unit of the robot through the docking contacts. This trigger can be connected to an irrigation computer, of a standard irrigation system, such as that for yards, courtyards, gardens, etc. One of the irrigation taps or ports can be set for the robot, and its activation will result in activation (initiation) of the robot for mowing. Accordingly, the scheduling of mowing can be set as one of the taps and programmed together with the irrigation schedule for the yard, courtyard, garden or the like. Scheduling for the activation of the triggering signal can be at any desired time, for example, when mowing is desired. This can be at daily, weekly or even monthly intervals, depending on the kind of mowing needed and the season of the year.

There has been shown and described at least one preferred embodiment of a docking station and robot for use therewith. It is apparent to those skilled in the art, however, that many changes, variations, modifications, and other uses and applications for the apparatus and its components are possible, and also such changes, variations, modifications, and other uses and applications which do not depart from the spirit and scope of the invention are deemed to be covered by the invention, which is limited only by the claims which follow.

What is claimed is:

1. A robot comprising:

at least one contact, at least a portion of the contact extending from the robot; a control system in communication with the at least one contact;

a power supply for the robot, the power supply in communication with the control system and the at least one contact, and

the control system is configured for permitting recharging of the power supply through the at least one contact when a predetermined voltage on the at least one contact is detected.

- 2. The robot of claim 1, wherein the predetermined voltage is at least a threshold voltage.
- 3. The robot of claim 2, wherein the threshold voltage is approximately 25 Volts.
- 4. The robot of claim 1, wherein the at least one contact includes two contacts.

5. A docking station comprising:

a portion configured for receiving a robot; and

a system for providing power to the robot for recharging the robot, the system including receptors configured for contacting at least one docking contact on the robot and transmitting a predetermined voltage therethrough.

- 6. The docking station of claim 5, wherein the receptors include at least one leaf.
- 7. The docking station of claim 5, additionally comprising:

a control system in communication with the power providing system, the control system configured for communication with at least one tap of an irrigation system, the tap being timer controlled, and coupled with the receptor for sending a signal to the robot for initiating operation of the robot.

Attorney Docket No. 67014 Page 11 of 12

- 8. The docking station of claim 5, wherein the predetermined voltage is at least a threshold voltage, that causes the control system of the robot to recognize docking between the robot and the docking station to initiate recharging of the robot.
- 9. The docking station of claim 5, wherein the at least one docking contact on the robot includes two docking contacts and the receptors of are configured for contacting the two docking contacts on the robot and transmitting the predetermined voltage therethrough.
